## BRF6300 WSP Package Information

January 2, 2007  
BT-AN-0063, Revision 0.2

---

### 1. Overview

This document outlines the package information of the NanoStar package used in Texas Instruments BRF6300 chip. This information includes the package parameters that are of importance in the manufacturing process like PCB design guidelines, reflow profile and lead free information.

Daisy chain devices that match the BRF6300 packages are intended to give customers the ability to perform reliability test during the ramp up and mass production phases.

### 2. Introduction

The parallel pursuit of cost reduction and miniaturization in recent years has given rise to an increasing emphasis on very small integrated circuit (IC) package solutions.

This is particularly evident in consumer-based end equipment using digital signal processor (DSP) solutions such as wireless telephones, laptop computers, and hard-disk drives. Despite the formal definition, packages with an area similar in size to the IC they encapsulate are loosely referred to as chip scale packages (CSPs).

Chip scale packages are in many ways an ideal solution to the cost reduction and miniaturization requirements.

Texas Instruments produces a family of CSPs called NanoStar Wafer Chip-Scale Packages (WCSP). Like most other CSPs, NanoStar packages use solder alloy balls as the interconnect between the IC and the board on which the package is soldered. The NanoStar family comes in a range of solder ball pitch (0.5 mm and 0.4 mm).

The NanoStar package has been fully qualified in numerous applications and is being used extensively in mobile phones, laptops, modems, handheld devices, and office environment equipment.

Daisy-chained units are used to gain experience in the testing, to check PCB electrical layouts, and to confirm the accuracy of the mounting equipment.

To facilitate this, Texas Instruments offers daisy-chained units in all production NanoStar packages.

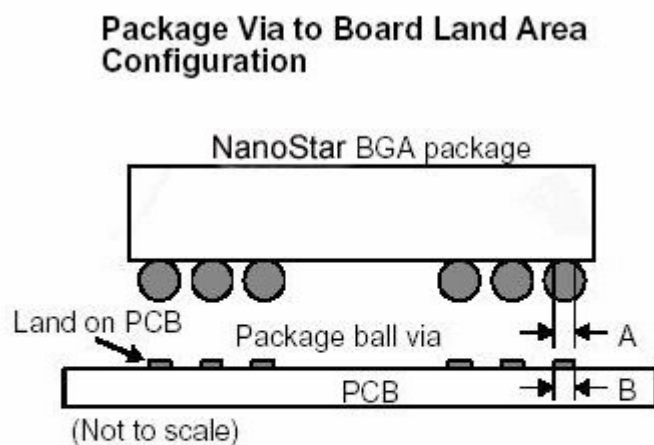

Reliability is one of the first questions designers ask about any new packaging technology. They want to know how well the package will survive handling and assembly operation, and how long it will last on the board.

The elements of package reliability and system reliability, while related, focus on different material properties and characteristics and are tested by different methods.

### 3. PCB Design Constraints

#### 3.1 Solder Land Areas

Design of both the NanoStar Package itself and the printed circuit board (PCB) are important in achieving good manufacturability and optimum reliability. In particular, the diameters of the package vias and the board lands are critical. While the actual sizes of these dimensions are important, their ratio is more critical. Figure 1 illustrates the package via-to-PCB configuration and Figure 2 illustrates why this ratio is critical.

A = Via diameter on package

B = Land diameter on PCB

Ratio A/B should equal 1.0 for optimum reliability.

Figure 1: Package Via to Board Land Area Configuration

## Effects of Via-to-Land Ratios

Figure 2: Effects of Via-to-Land Ratios

In the top view of Figure 2, the package via is larger than the PCB via, and the solder ball is prone to crack prematurely at the PCB interface. In the middle view, the PCB via is larger than the package via, which leads to cracks at the package surface. In the bottom view, where the ratio is almost 1:1, the stresses are equalized and neither site is more susceptible to cracking than the other.

Solder lands on the PCB are generally simple round pads. Solder lands are either solder-mask-defined or non-solder-mask-defined.

**Solder-mask-defined (SMD) land.** With this method, the copper pad is made larger than the desired land area, and the opening size is defined by the opening in the solder mask material. The advantages normally associated with this technique include more closely controlled size and better copper adhesion to the laminate. Better size control is the result of photoimaging the stencils for masks. The chief disadvantage of this method is that the larger copper spot can make routing more difficult.

**Non-solder-mask-defined (NSMD) land.** Here, the land area is etched inside the solder mask area. While the size control is dependent on copper etching and is not as accurate as the solder mask method, the overall pattern registration is dependent on the copper artwork, which is quite accurate. The tradeoff is between accurate dot placement and accurate dot size. TI recommends non solder mask defined pads for NanoStar packages.

See Figure 3 for an example of optimum land diameters and configurations (in mm) for a common NanoStar pitch.

Solder Mask Defined

Non Solder Mask Defined

Ball Pitch		PWB Design		Stencil Design	
		A	B	Thickness	Opening
0.5mm	SMD	0.30	0.35	0.10	0.30
	NSMD	0.30	0.25	0.10	0.30

**NOTE:** We don't recommend using "U" shape PWB land because of trapping void during reflow.

Figure 3: Optimum Land Configurations

## 4. Reliability

### 4.1 Daisy Chain Units

Daisy-chained units are used to gain experience in the handling and mounting of CSPs, for board-reliability testing, to check PCB electrical layouts, and to confirm the accuracy of the mounting equipment. To facilitate this, Texas Instruments offers daisy-chained units in all production NanoStar packages, including the BRF6300.

Each daisy-chained pinout differs slightly depending on package layout. Daisy-chained packages are wired to provide a continuous path through the package for easy testing.

TI issues a net list for each package, which correlates each ball position with a corresponding wire pad number. The daisy-chained net list is a special case of the general net list.

When a daisy-chained package is assembled on the PCB, a complete circuit is formed, which allows continuity testing. The circuit includes the solder balls, the metal pattern on the die, the bond wires, and the PCB traces. The entire package or only a quadrant can be interconnected and tested. A diagram of the test configuration is shown in Figure 9.

Figure 4: Daisy Chain Test Configuration

### 4.2 Reliability data

Reliability is one of the first questions designers ask about any new packaging technology. They want to know how well the package will survive handling and assembly operation, and how long it will last on the board. The elements of package reliability and system reliability, while related, focus on different material properties and characteristics and are tested by different methods.

Package reliability focuses on materials of construction, thermal flows, material adherence/delamination issues, resistance to high temperatures, moisture resistance and ball/stitch bond reliability. Thorough engineering of the package is performed to prevent delamination caused by the interaction of the substrate material and the mold compound.

TI subjects each NanoStar to rigorous qualification testing before the package is released to production.

These tests are summarized in Table 1. All samples used in these tests are preconditioned according to Joint Electronic Device Committee (JEDEC) A113 at various levels. Typical data is presented in Table 2. NanoStar packages have proven robust and reliable.

Board-level reliability (BLR) issues generally focus on the complex interaction of various materials under the influence of heat generated by the operation of electronic devices. Not only is there a complex thermal situation caused by multiple heat sources, but there are cyclical strains due to expansion mismatches, warping and transient conditions, non-linear material properties, and solder fatigue behavior influenced by geometry, metallurgy, stress relaxation phenomenon, and cycle conditions. In addition to material issues, board and package design can influence reliability. Thermal management from a system level is critical for optimum reliability, and thermal cycling tests are generally used to predict behavior and reliability. Many of these are used in conjunction with solder fatigue life models using a

## 5. Surface Mounting NanoStar WCSP Packages

Surface-mount technology (SMT) has evolved over the past decade from an art into a science with the development of design guidelines and rules. While these guidelines are specific enough to incorporate many shared conclusions, they are general enough to allow flexibility in board layouts, solder pastes, stencils, fixturing and reflow profiles. From experience, most assembly operations have found NanoStar packages to be robust, manufacturing-friendly packages that fit easily within existing processes and profiles. In addition, they do not require special handling. However, as ball pitch becomes smaller, layout methodology and placement accuracy become more critical. Below is a review of the more important aspects of surface-mounted CSPs. The suggestions provided may aid in efficient, cost-effective production.

### 5.1 Design for Manufacturability

A well-designed board that follows the basic surface-mount technology considerations greatly improves the cost, cycle time, and quality of the end product. Board design should comprehend the SMT-automated equipment used for assembly, including minimum and maximum dimensional limits and placement accuracy. Many board shapes can be accommodated, but the front of the board should have a straight and square edge to help machine sensors detect it. While odd-shaped or small boards can be assembled, they require panelization or special tooling to process in-line. The more irregular the board—non-rectangular with no cutouts—the more expensive the assembly cost.

The following guidelines may be helpful:

- Automated equipment requires a minimum of two and preferably three fiducials.
- A wide range of fiducial shapes and sizes can be used. Among the most useful is a circle 1.6 mm in diameter with an annulus of 3.175/3.71 mm. The outer ring is optional, but no other feature may be within 0.76 mm of the fiducial.
- The most useful placement for the fiducials is an L configuration, which is orthogonal to optimize the stretch/shrink algorithms. When possible, the lower left fiducial should be the design origin (coordinate 0, 0).
- All components should be within 101.6 mm of a fiducial to guarantee placement accuracy. For large boards or panels, a fourth fiducial should be added.

If the edges of the boards are to be used for conveyer transfer, a cleared zone of at least 3.17 mm should be allowed. Normally, the longest edges of the board are used for this purpose, and the actual width is dependent on equipment capability. While no component lands or fiducials can be in this area, breakaway tabs may be.

Interpackage spacing is a key aspect of DFM, and the question of how close you can safely put components to each other is a critical one. The following component layout considerations are recommendations based on TI experience:

- There should be a minimum of 0.508 mm between land areas of adjacent components to reduce the risk of shorting.
- The recommended minimum spacing between SMD discrete component bodies is equal to the height of the tallest component. This allows for a 45° soldering angle in case manual work is needed.
- Polarization symbols need to be provided for discrete SMDs (diodes, capacitors, etc.) next to the positive pin.
- Pin-1 indicators or features are needed to determine the keying of SMD components.
- Space between lands (under components) on the backside discrete components should be a minimum of 0.33 mm. No open vias may be in this space.
- The direction of backside discretes for wave solder should be perpendicular to the direction through the wave.
- Do not put SMT components on the bottom side that exceed 200 grams per square inch of contact area with the board.
- If space permits, symbolize all reference designators within the land pattern of the respective components.
- It is preferable to have all components oriented in well-ordered columns and rows.
- Group similar components together whenever possible.
- Room for testing needs to be allowed.

### **5.2 Solder Paste**

TI recommends the use of paste when mounting NanoStar packages. The use of paste offers the following advantages:

- It acts as a flux to aid wetting of the solder ball to the PCB land.
- The adhesive properties of the paste will hold the component in place during reflow.
- It helps compensate for minor variations in the planarity of the solder balls.
- Paste contributes to the final volume of solder in the joint, and thus allows this volume to be varied to give an optimum joint.

Paste selection is normally driven by overall system assembly requirements. In general, the “no clean” compositions are preferred due to the difficulty in cleaning under the mounted component. Most assembly operations have found that no changes in existing pastes are required by the addition of MicroStar BGA, but due to the large variety of board designs and tolerances, it is not possible to say this will be true for any specific application.

Nearly as critical as paste selection is stencil design. A proactive approach to stencil design can pay large dividends in assembly yields and lower costs. In general, NanoStar packages are special cases of BGA packages, and the general design guidelines for BGA package assembly applies to them as well.

The typical stencil hole diameter should be the same size as the land area, and 100-120- $\mu$ m-thick stencils have been found to give the best results. Good release and a consistent amount of solder paste and shapes are critical, especially as ball pitches decrease. The use of metal squeegee blades, or at the very least, high durometer polyblades, is important in achieving this.

Paste viscosity and consistency during screening are some variables that require close control.

### **5.3 Solder Ball Collapse**

In order to produce the optimum solder joint, it is important to understand the amount of collapse of the solder balls, and the overall shape of the joint. These are a function of:

- The diameter of the package solder ball via.
- The volume and type of paste screened onto the PCB.
- The diameter of the PCB land.
- The board assembly reflow conditions.
- The weight of the package.

The original ball height on the package for a typical 0.4-mm-pitch package is 0.21 mm. After the package is mounted, this typically drops to 0.17 mm, as illustrated in Figure 5.

Figure 5: Solder Ball Collapse

Controlling the collapse, and thus defining the package standoff, is critical to obtaining the optimum joint reliability. Generally, a larger standoff gives better solder joint fatigue strength, but this should not be achieved by reducing the board land diameter. Reducing the land diameter will increase the standoff, but will also reduce the minimum cross-section area of the joint. This, in turn, will increase the maximum shear force at the PCB side of the solder joint. Thus, a reduction of land diameter will normally result in a worse fatigue life, and should be avoided unless all the consequences are well understood.

## 5.4 Reflow

Solder reflow conditions are the next critical step in the mounting process. During reflow, the solvent in the solder paste evaporates, the flux cleans the metal surfaces, the solder particles melt, wetting of the surfaces takes place by wicking of molten solder, the solder balls collapse, and finally solidification of the solder into a strong metallurgical bond completes the process. The desired end result is a uniform solder structure strongly bonded to both the PCB and the package with small or no voids and a smooth, even fillet at both ends. Conversely, when all the steps do not carefully fit together, voids, gaps, uneven joint thickness, discontinuities, and insufficient fillet can occur. While the exact cycle used depends on the reflow system and paste composition, there are several key points all successful cycles have in common.

The first of these is a warm-up period sufficient to safely evaporate the solvent. This can be done with a pre-heat or a bake, or, more commonly, a hold in the cycle at evaporation temperatures. If there is less solvent in the paste (such as in a high-viscosity, high-metal-content paste), then the hold can be shorter. However, when the hold is not long enough to get all the solvent out or too fast to allow it to evaporate, several negative things happen. These range from solder-particle splatter to trapped gases, which can cause voids and embrittlement. A significant number of reliability problems with solder joints can be solved with the warm-up step, so it needs careful attention.

The second key point that successful reflow cycles have in common is uniform heating across the package and the board. Uneven solder thickness and non-uniform solder joints may be an indicator that the profile needs adjustment. There can also be a problem when different sized components are reflowed at the same time. Care needs to be taken when profiling an oven to be sure that the indicated temperatures are representative of what the most difficult to reflow

## BRF6300 WSP Package Information

January 2, 2007  
BT-AN-0063, Revision 0.2

parts are seeing. These problems are more pronounced with some reflow methods, such as infrared (IR) reflow, than with others, such as forced hot-air convection.

Finally, successful reflow cycles strike a balance among temperature, timing, and length of cycle. Mistiming may lead to excessive fluxing activation, oxidation, excessive voiding, or even damage to the package. Heating the paste too hot too fast before it melts can also dry the paste, which leads to poor wetting. Process development is needed to optimize reflow profiles for each solder paste/flux combination.

The profile shown in Figure 6: Recommended Reflow Profile below is the recommended profile for the BRF6300 NanoStar package.

Figure 6: Recommended Reflow Profile

## 5.5 Inspection

NanoStar packages have been designed to be consistent with very high-yield assembly processes. Because of their relatively light weight, NanoStar packages tend to self-align during reflow. Since the pitch of the ball pattern is large compared to that of fine-pitch leaded packages, solder bridging is rarely encountered. It is recommended that a high-quality solder joint assembly process be developed using the various inspection and analytical techniques, such as cross-sectioning.

Once a quality process has been developed, detailed inspection should not be necessary. Visual methods, while obviously limited, can offer valuable clues to the general stability of the process. Electrical checks can confirm interconnection. Both transmission X-rays and laminographic X-rays have proven to be useful nondestructive tools, if desired.

### **6. Lead Free Solutions**

Environmental concerns are driving the need for lead-free solutions to electronic components and systems. Texas Instruments (TI) has been a leader in working with our customers to provide them with products, which meet their specific needs. The first practical lead-free alternative was the Nickel/Palladium (Ni/Pd) finish introduced by TI in 1989. Since then, more than 30 billion lead-free Ni/Pd components have been supplied. Texas Instruments continues to be active in this field, working with other manufacturers to evaluate other lead-free finishes to understand their manufacturability and reliability.

Continuing this position of leadership, TI has introduced a lead-free solder ball option for the NanoStar packages. Texas Instruments is also evaluating lead-free solder ball applications for other area array packages. In conjunction with this effort, TI is an active participant in the industry-wide effort to evaluate lead-free solder alloys and lead-free printing wiring board finishes. Several of the lead-free systems being proposed require a maximum reflow temperature higher than that needed with the Sn/Pb systems, so package and system reliability data must be developed. Securing the required Board Level Reliability (BLR) under various customer conditions depends on many factors: solder ball composition, solder paste, PCB design, land finish and reflow conditions.

The composition TI has selected for lead-free NanoStar packages is an Sn-Ag-Cu alloy. Reliability data presented in Table 9 shows it to be a robust performer, equivalent to the Sn/Pb eutectic balls it replaces.

Extensive assembly testing has shown it to be virtually indistinguishable from Sn/Pb eutectic ball performance in current systems and superior in high temperature, lead-free systems.

TI's name for lead-free NanoStar packages is NanoFree. The BRF6300 NanoFree packages are lead free (Green, RoHS6 & no Sb/Br).

Comment: due to the lead free the reflow temperature profile and peak temperature is higher than non-lead free packages, for exact reflow profile refer to Figure 6: Recommended Reflow .

#### **6.1 Moisture Sensitivity**

A drop of 3+ levels in moisture sensitivity (as per J-STD-20) has been indicated for several package types with the peak temperature of 260 °C. Extensive testing NanoFree packages has shown they are capable of resisting the 260 °C cycles without an impact on the moisture sensitivity classification.

## 7. Package Technical Details

### 7.1 Package information

Component ID code/number/name		
Package type and name	NanoStar 47YFA (3.19X3.19; 0.4mm pitch)	
Package marking	Component	TI logo
	Orientation	#A1 / bottom right corner
Package attributes	Ball count	47
	Ball pitch (mm)	0.45
	Ball diameter / dimensions (mm)	0.25 / 0.35
	Ball height / substrate standoff (mm)	0.12 / 0.30
	Coplanarity (mm)	0.05
	Package thickness (mm)	0.625 Max
	Package weight (g)	
	Max footprint (mm x mm)-center to center	2.40x2.40mm
	Die size, per side	Max die size= 3.23 X 3.23 mm
	Thickness	0.625 um max.
	Interconnect method (WB, TAB, FC)	FC
	Daisy chain level (if daisy chain component)	Level 3
	Available shipping media	Tape&Reel
	Components in one shipping package / in one dry package	Tape&Reel= 2500 / bag

### **Important Notice**

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, the customer to minimize inherent or procedural hazards must provide adequate design and operating safeguards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.
